HTTP

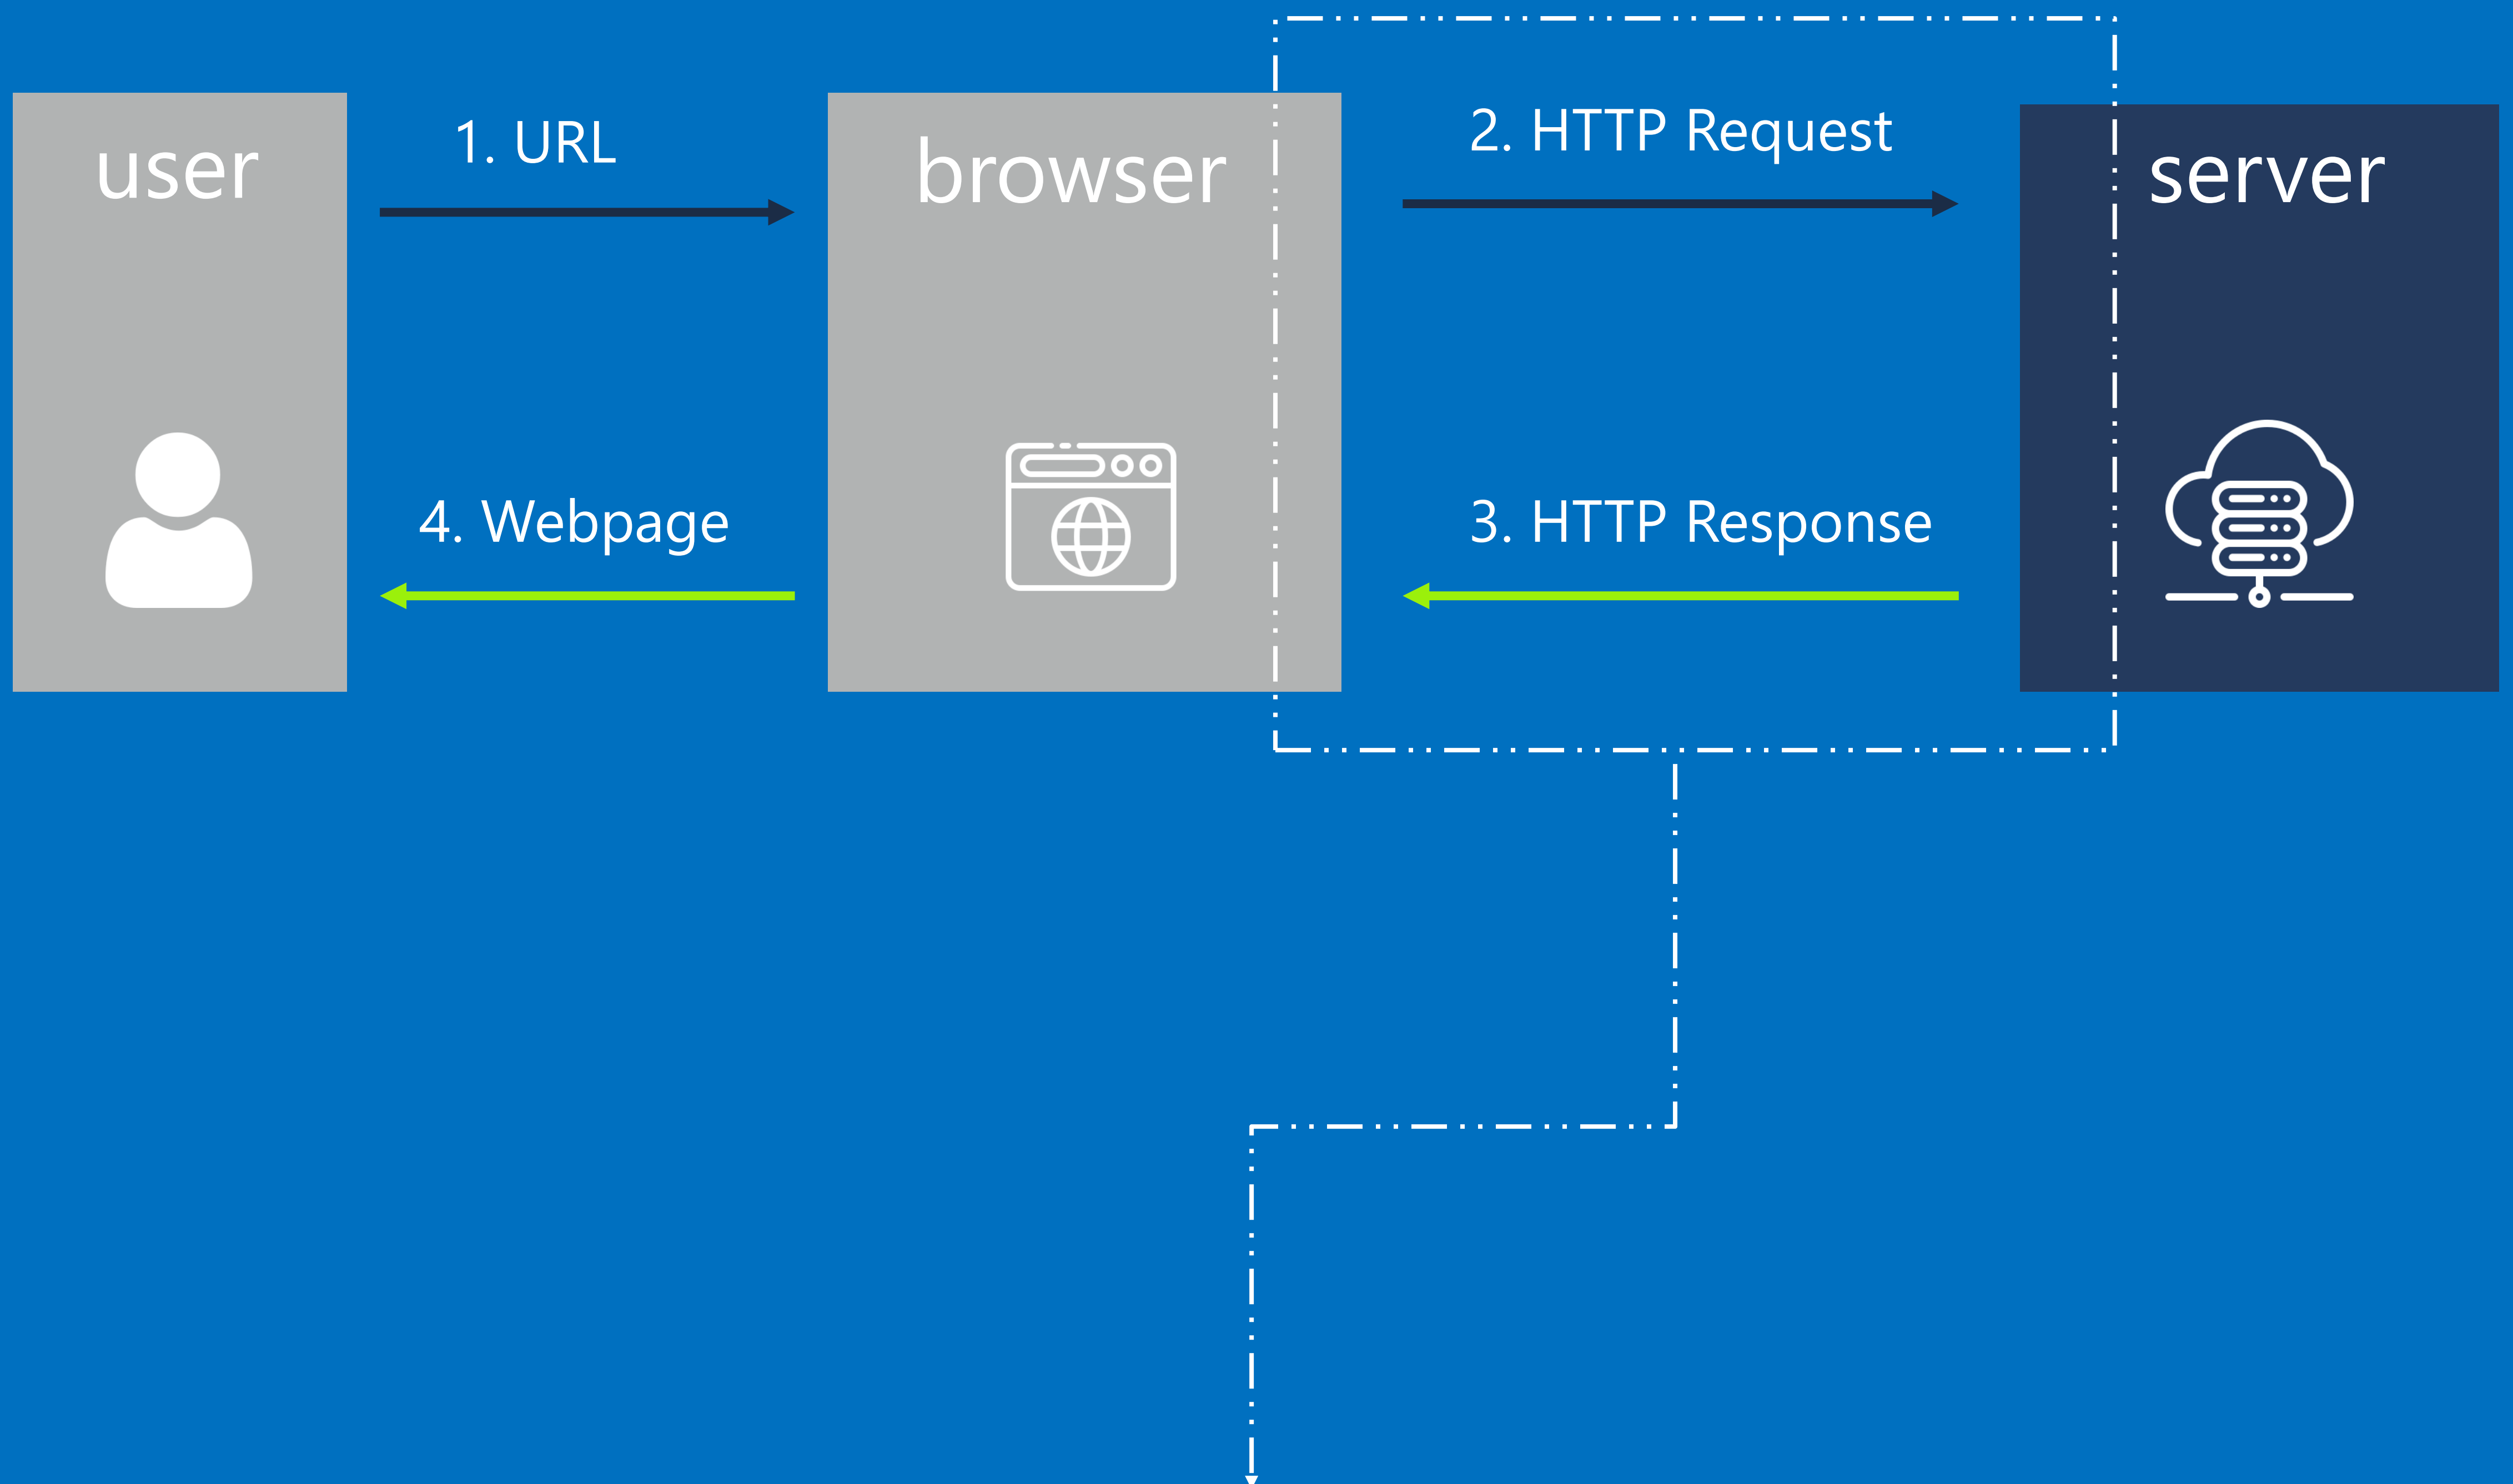

State

Management

SWIPE

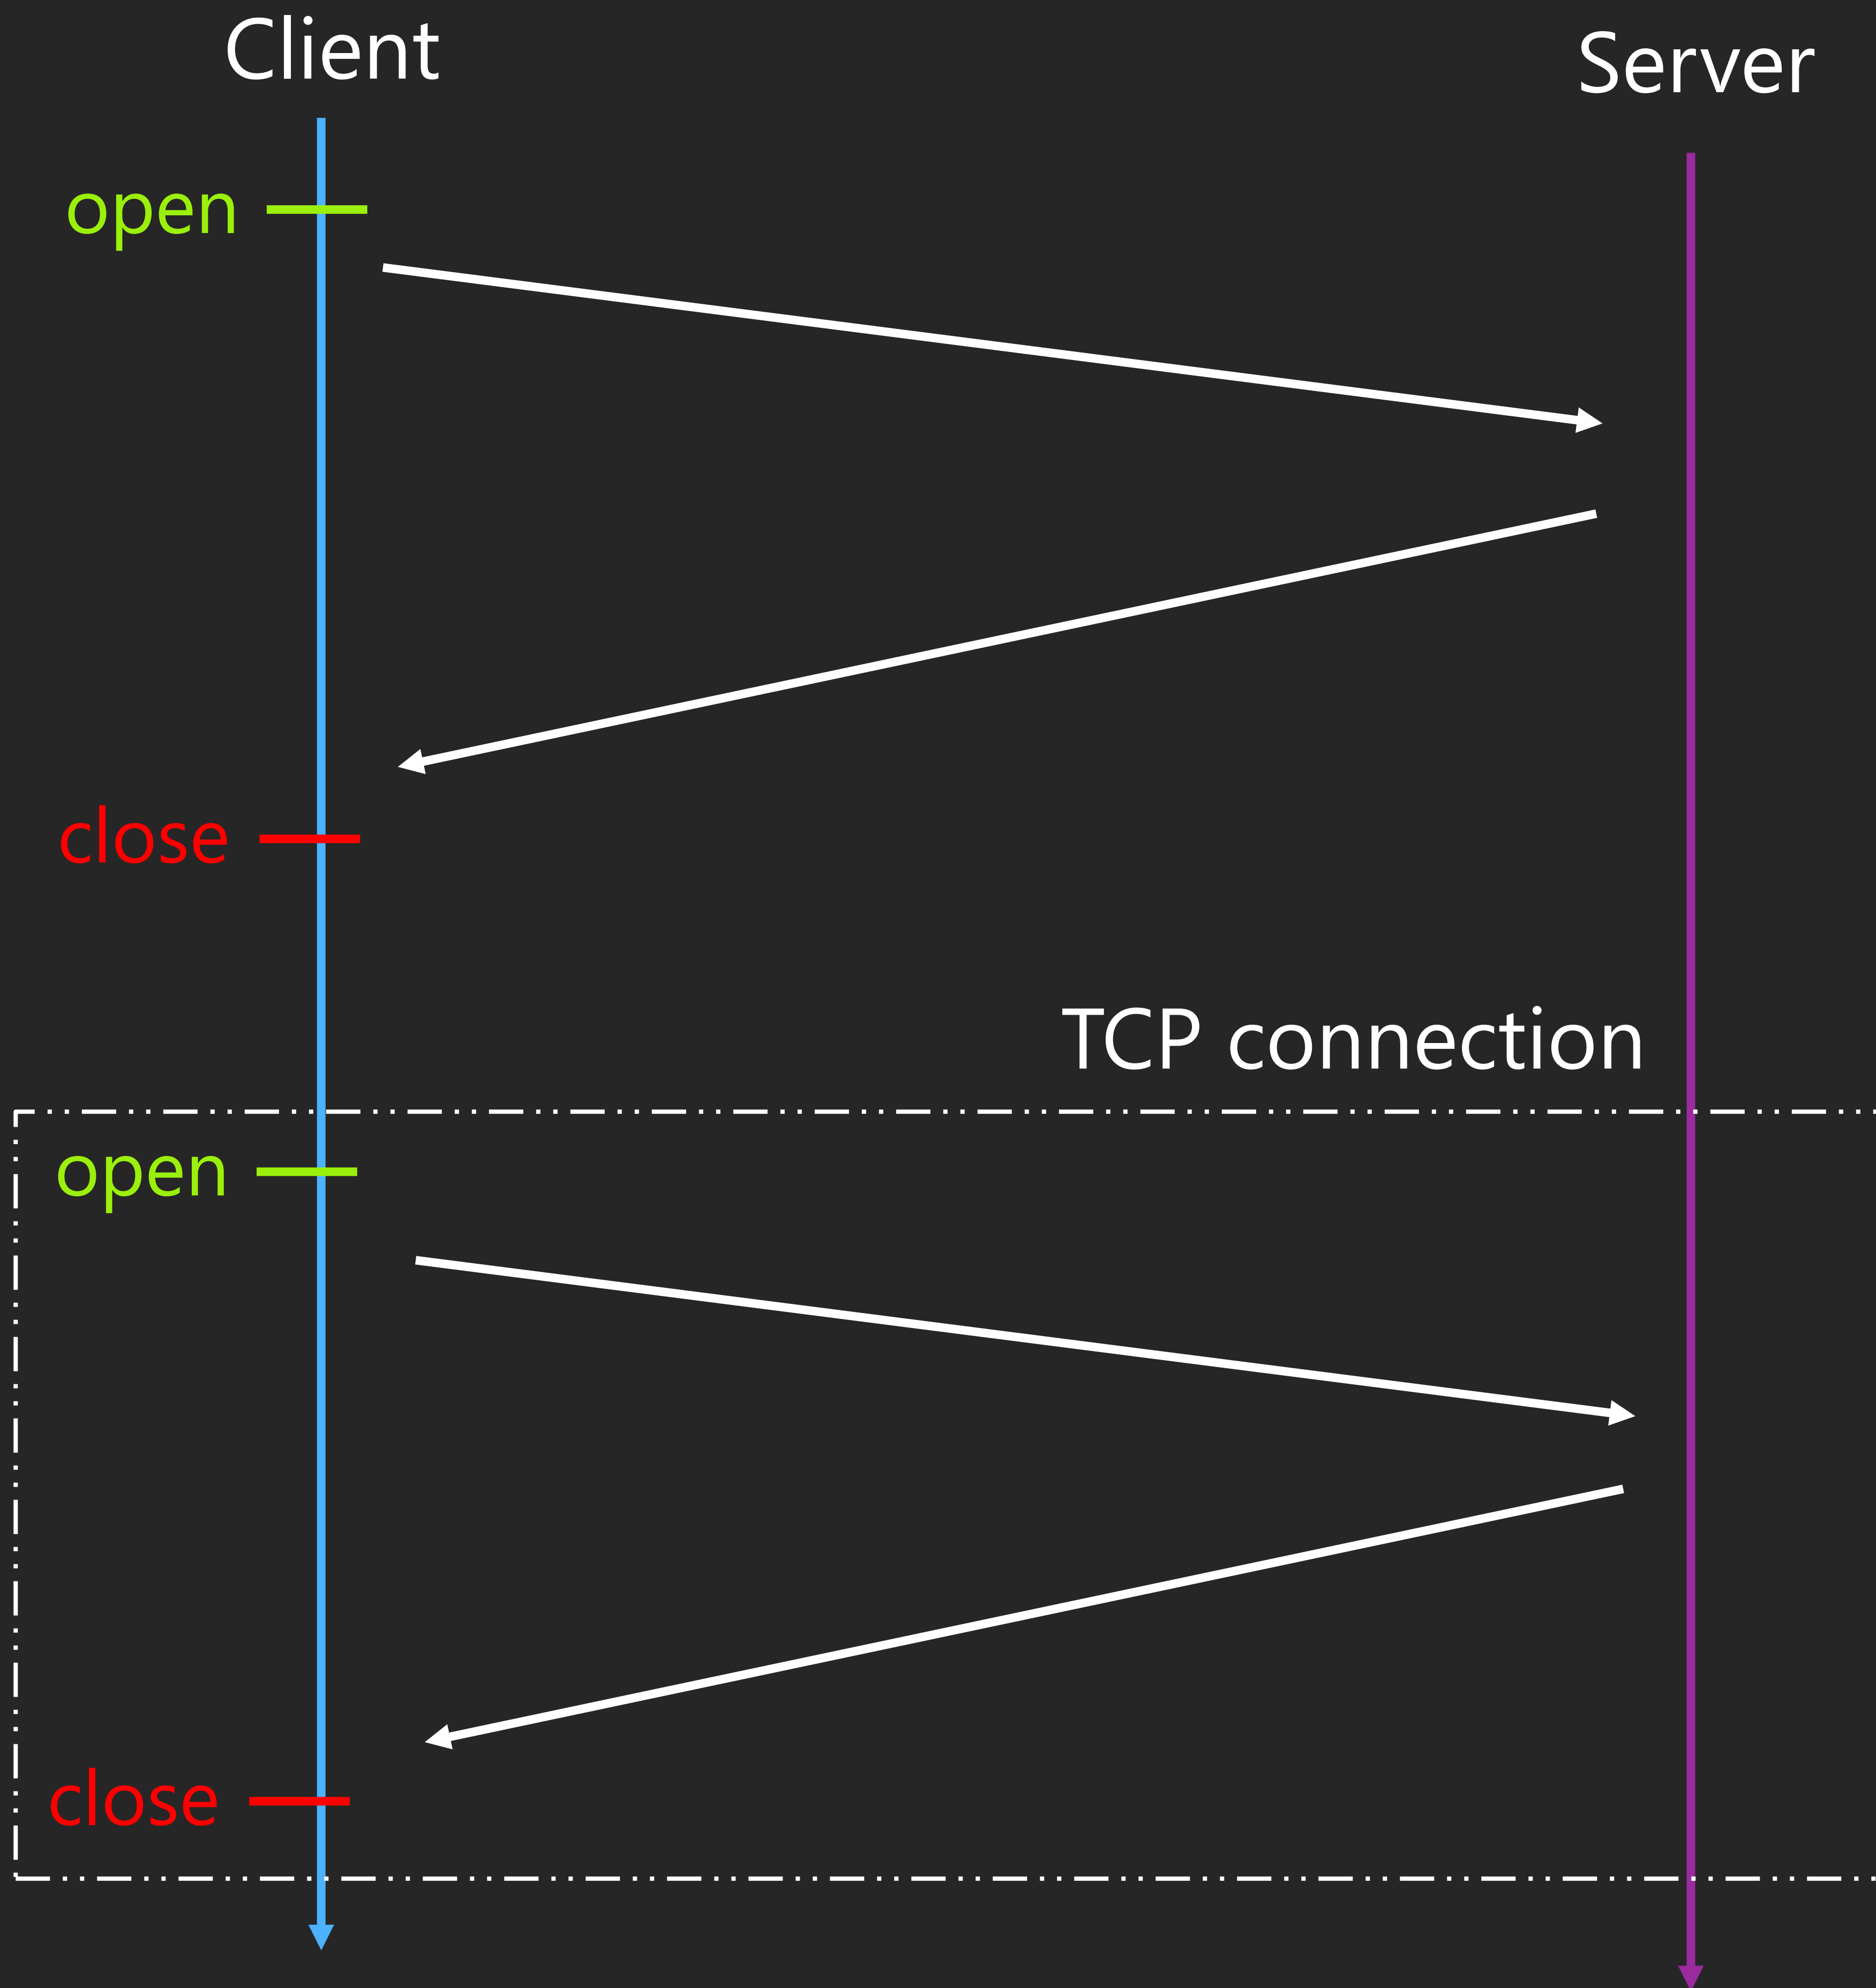

What is HTTP

HTTP is a protocol.

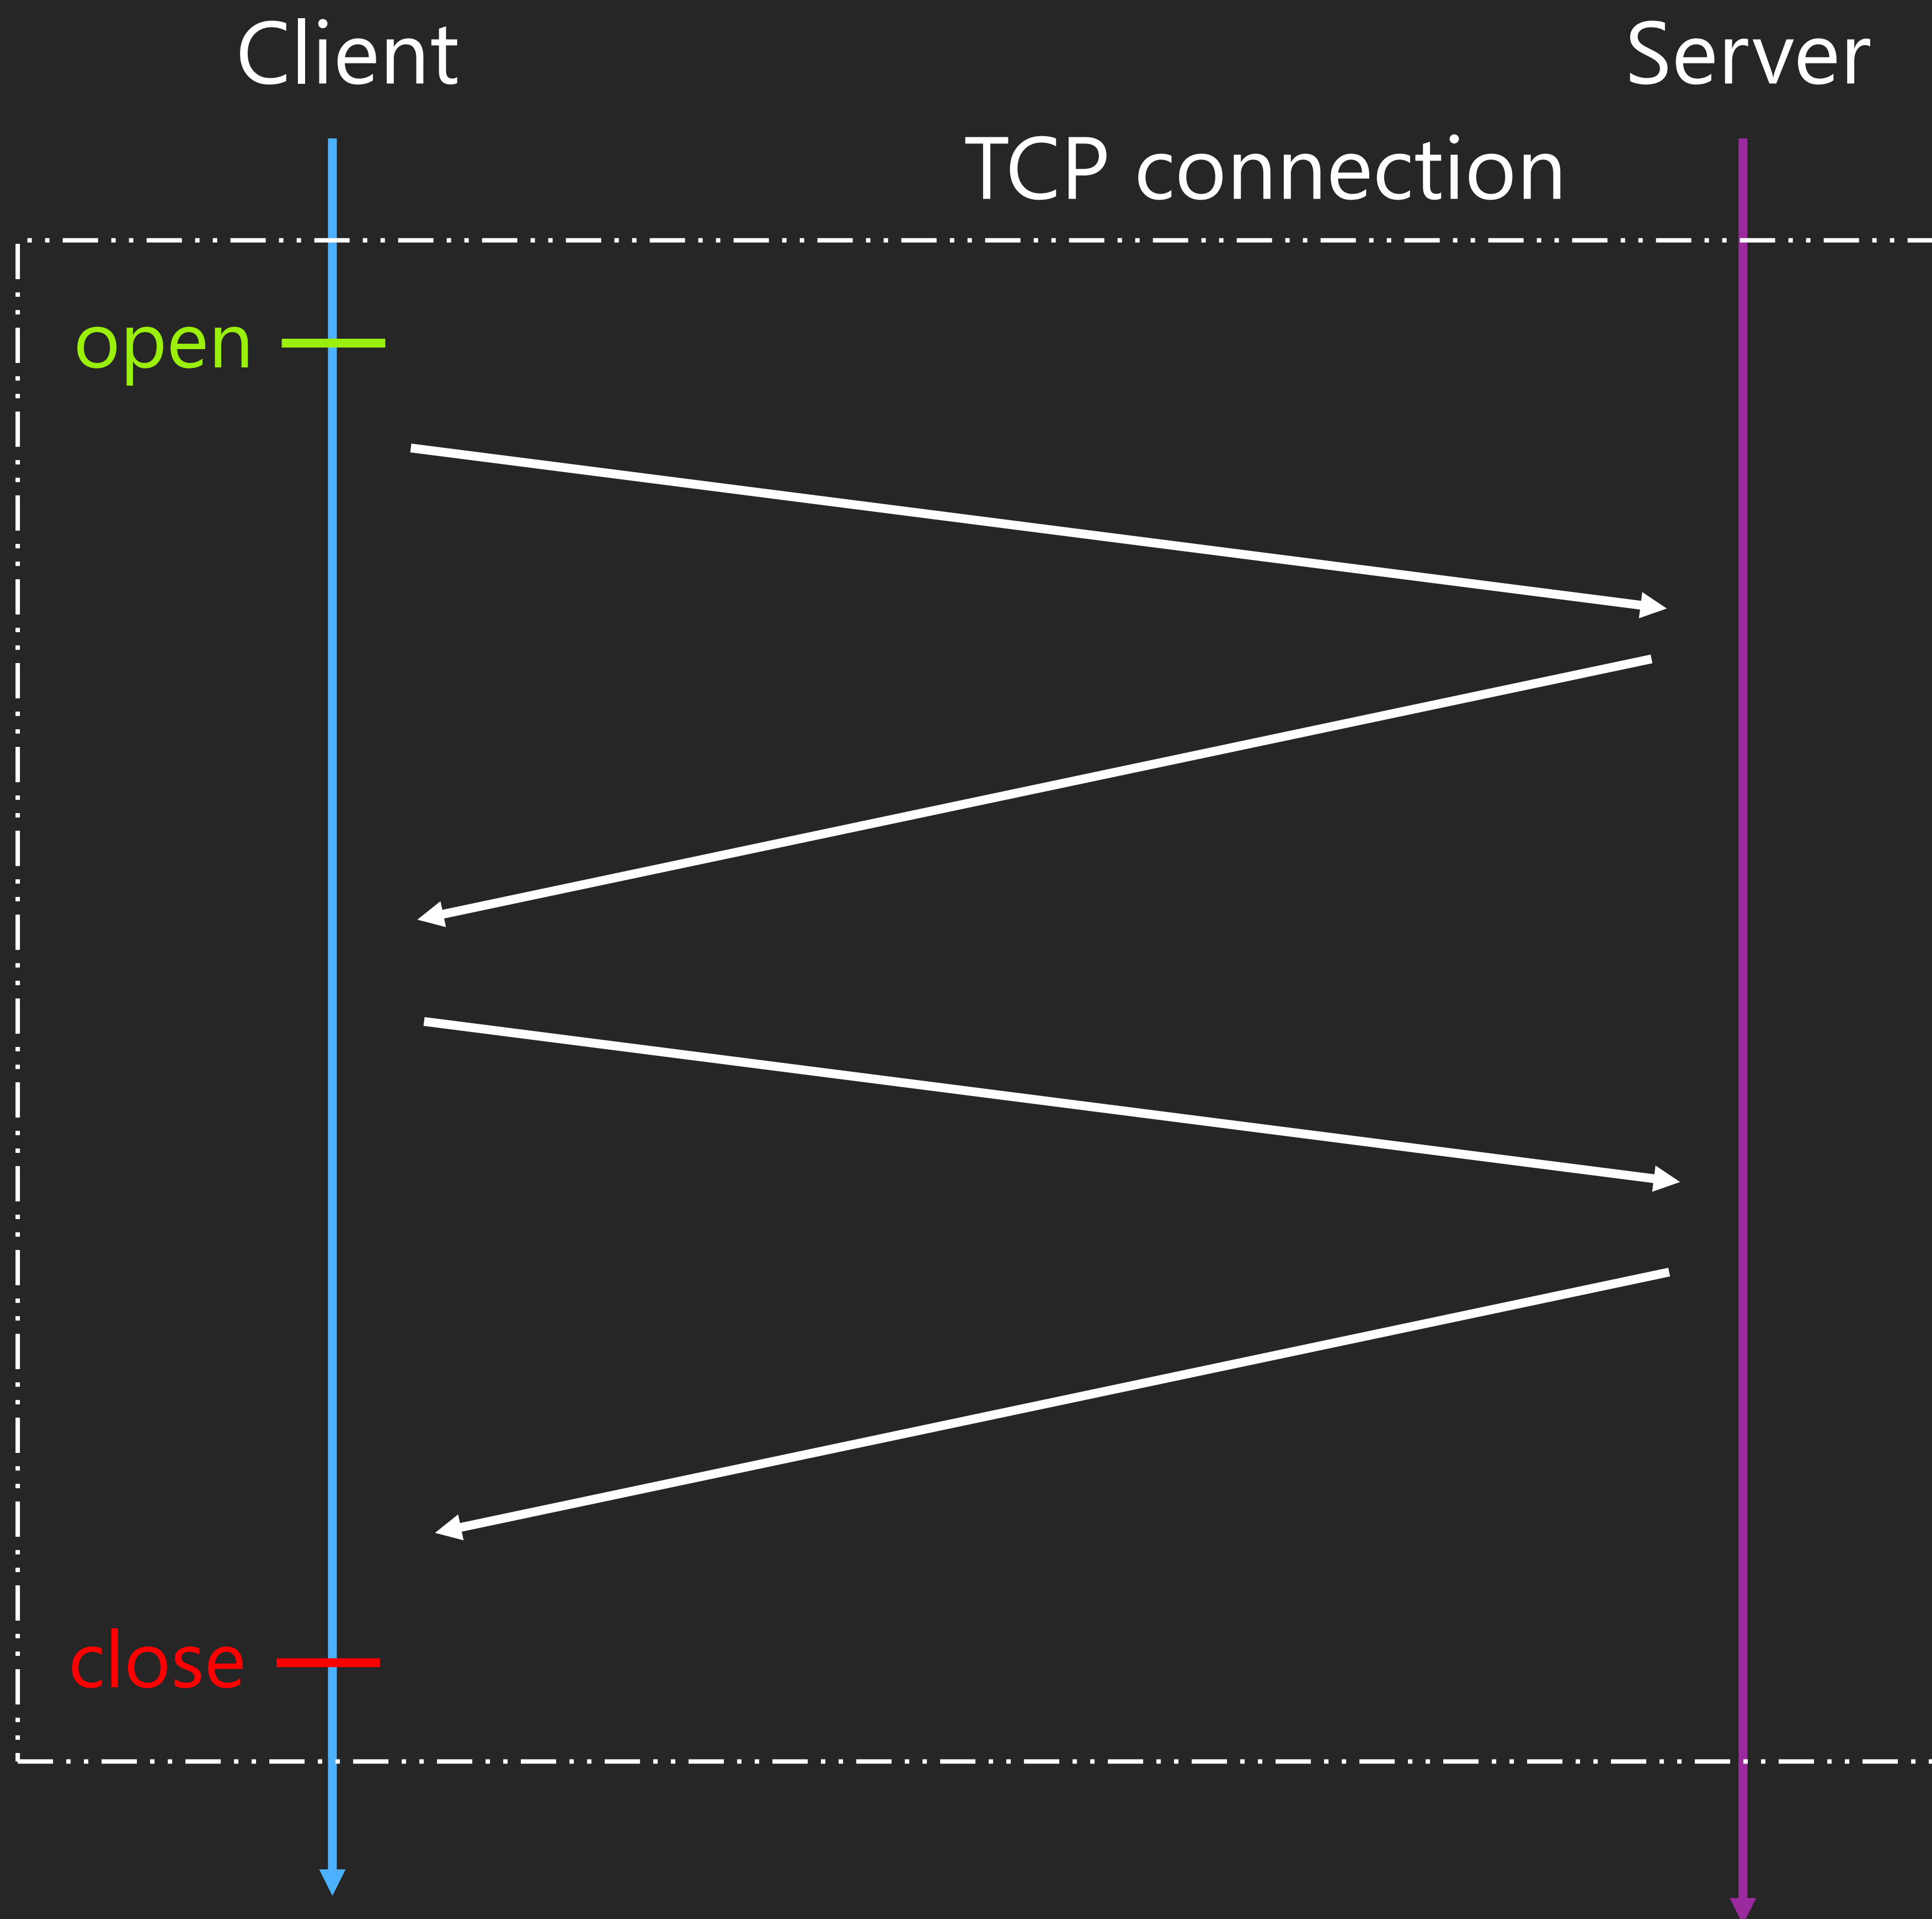

It allows web **browsers** and **servers** to communicate by exchanging requests and responses.

HTTP Multiple connections mode

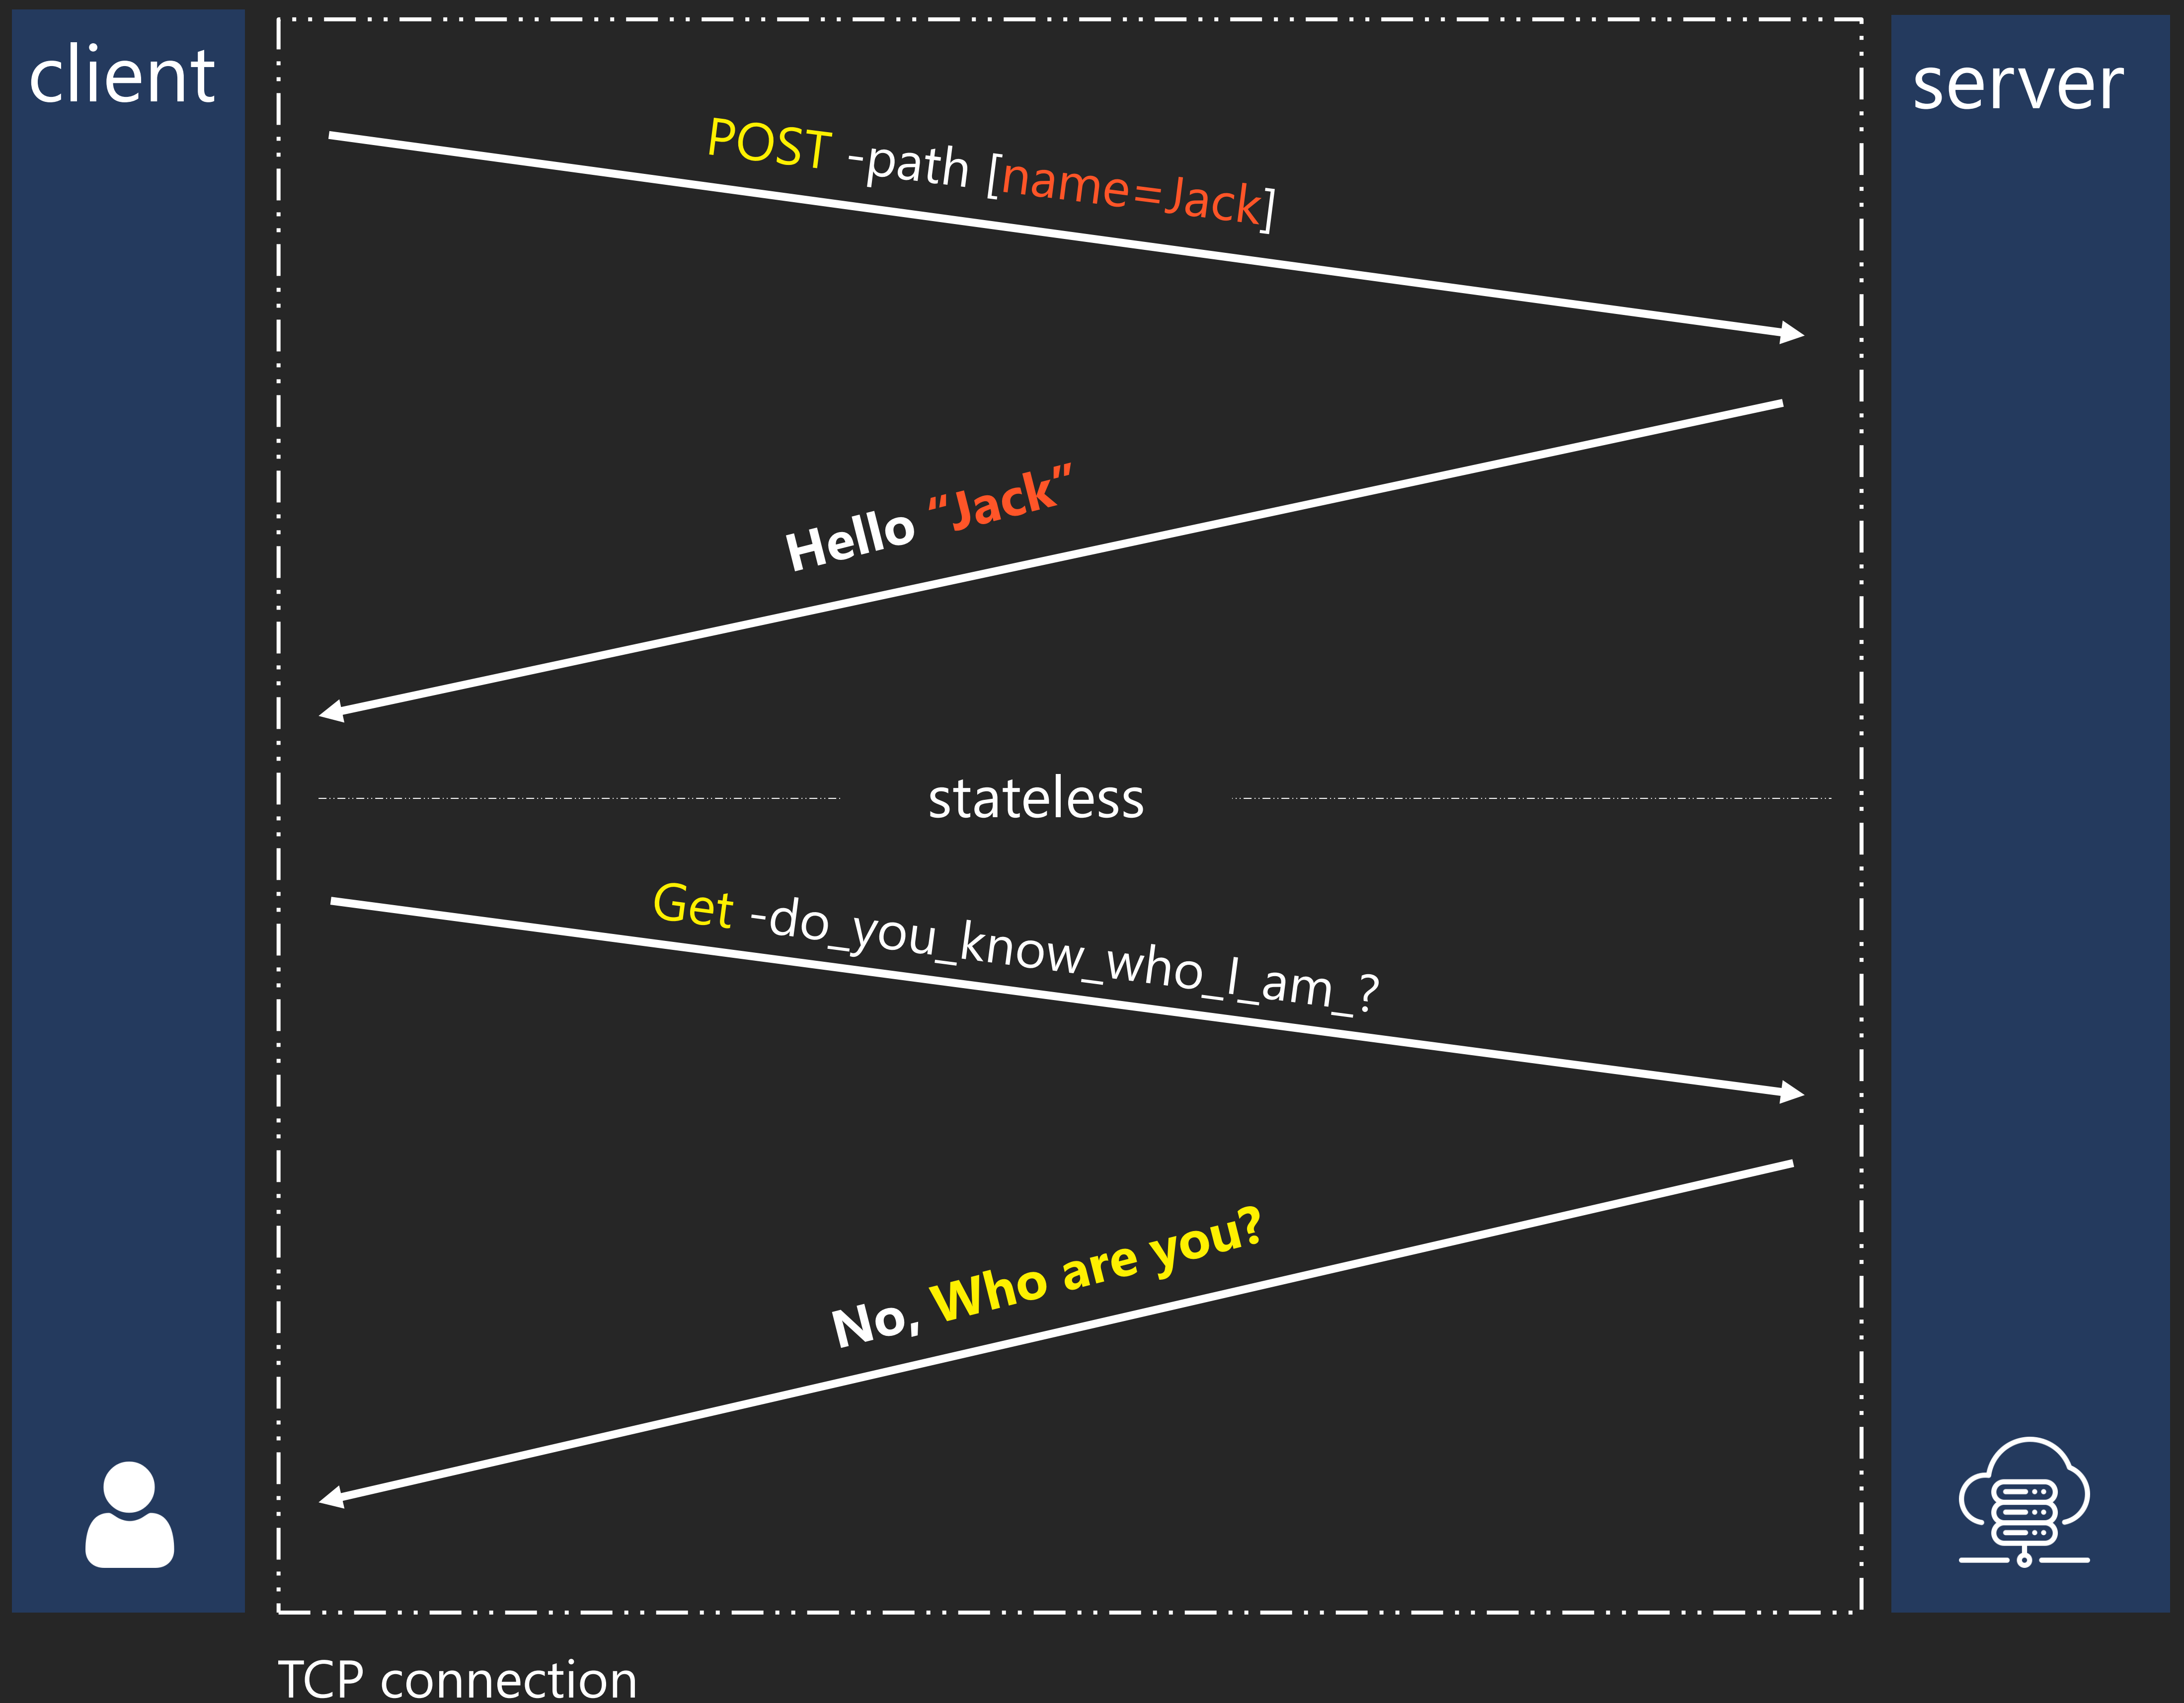

Using more than one **TCP connection** to send and receive HTTP requests and responses.

HTTP keep-alive mode

This allows a single TCP connection to remain open for multiple HTTP requests/responses.

HTTP is stateless!

Because it does not remember **anything** between **HTTP requests** in both of Multiple connections or Keep-alive modes.

HTTP state management

Is a mechanism that specifies a way to create a stateful session with HTTP requests and responses.

State can be stored using several approaches

Cookies

Session State

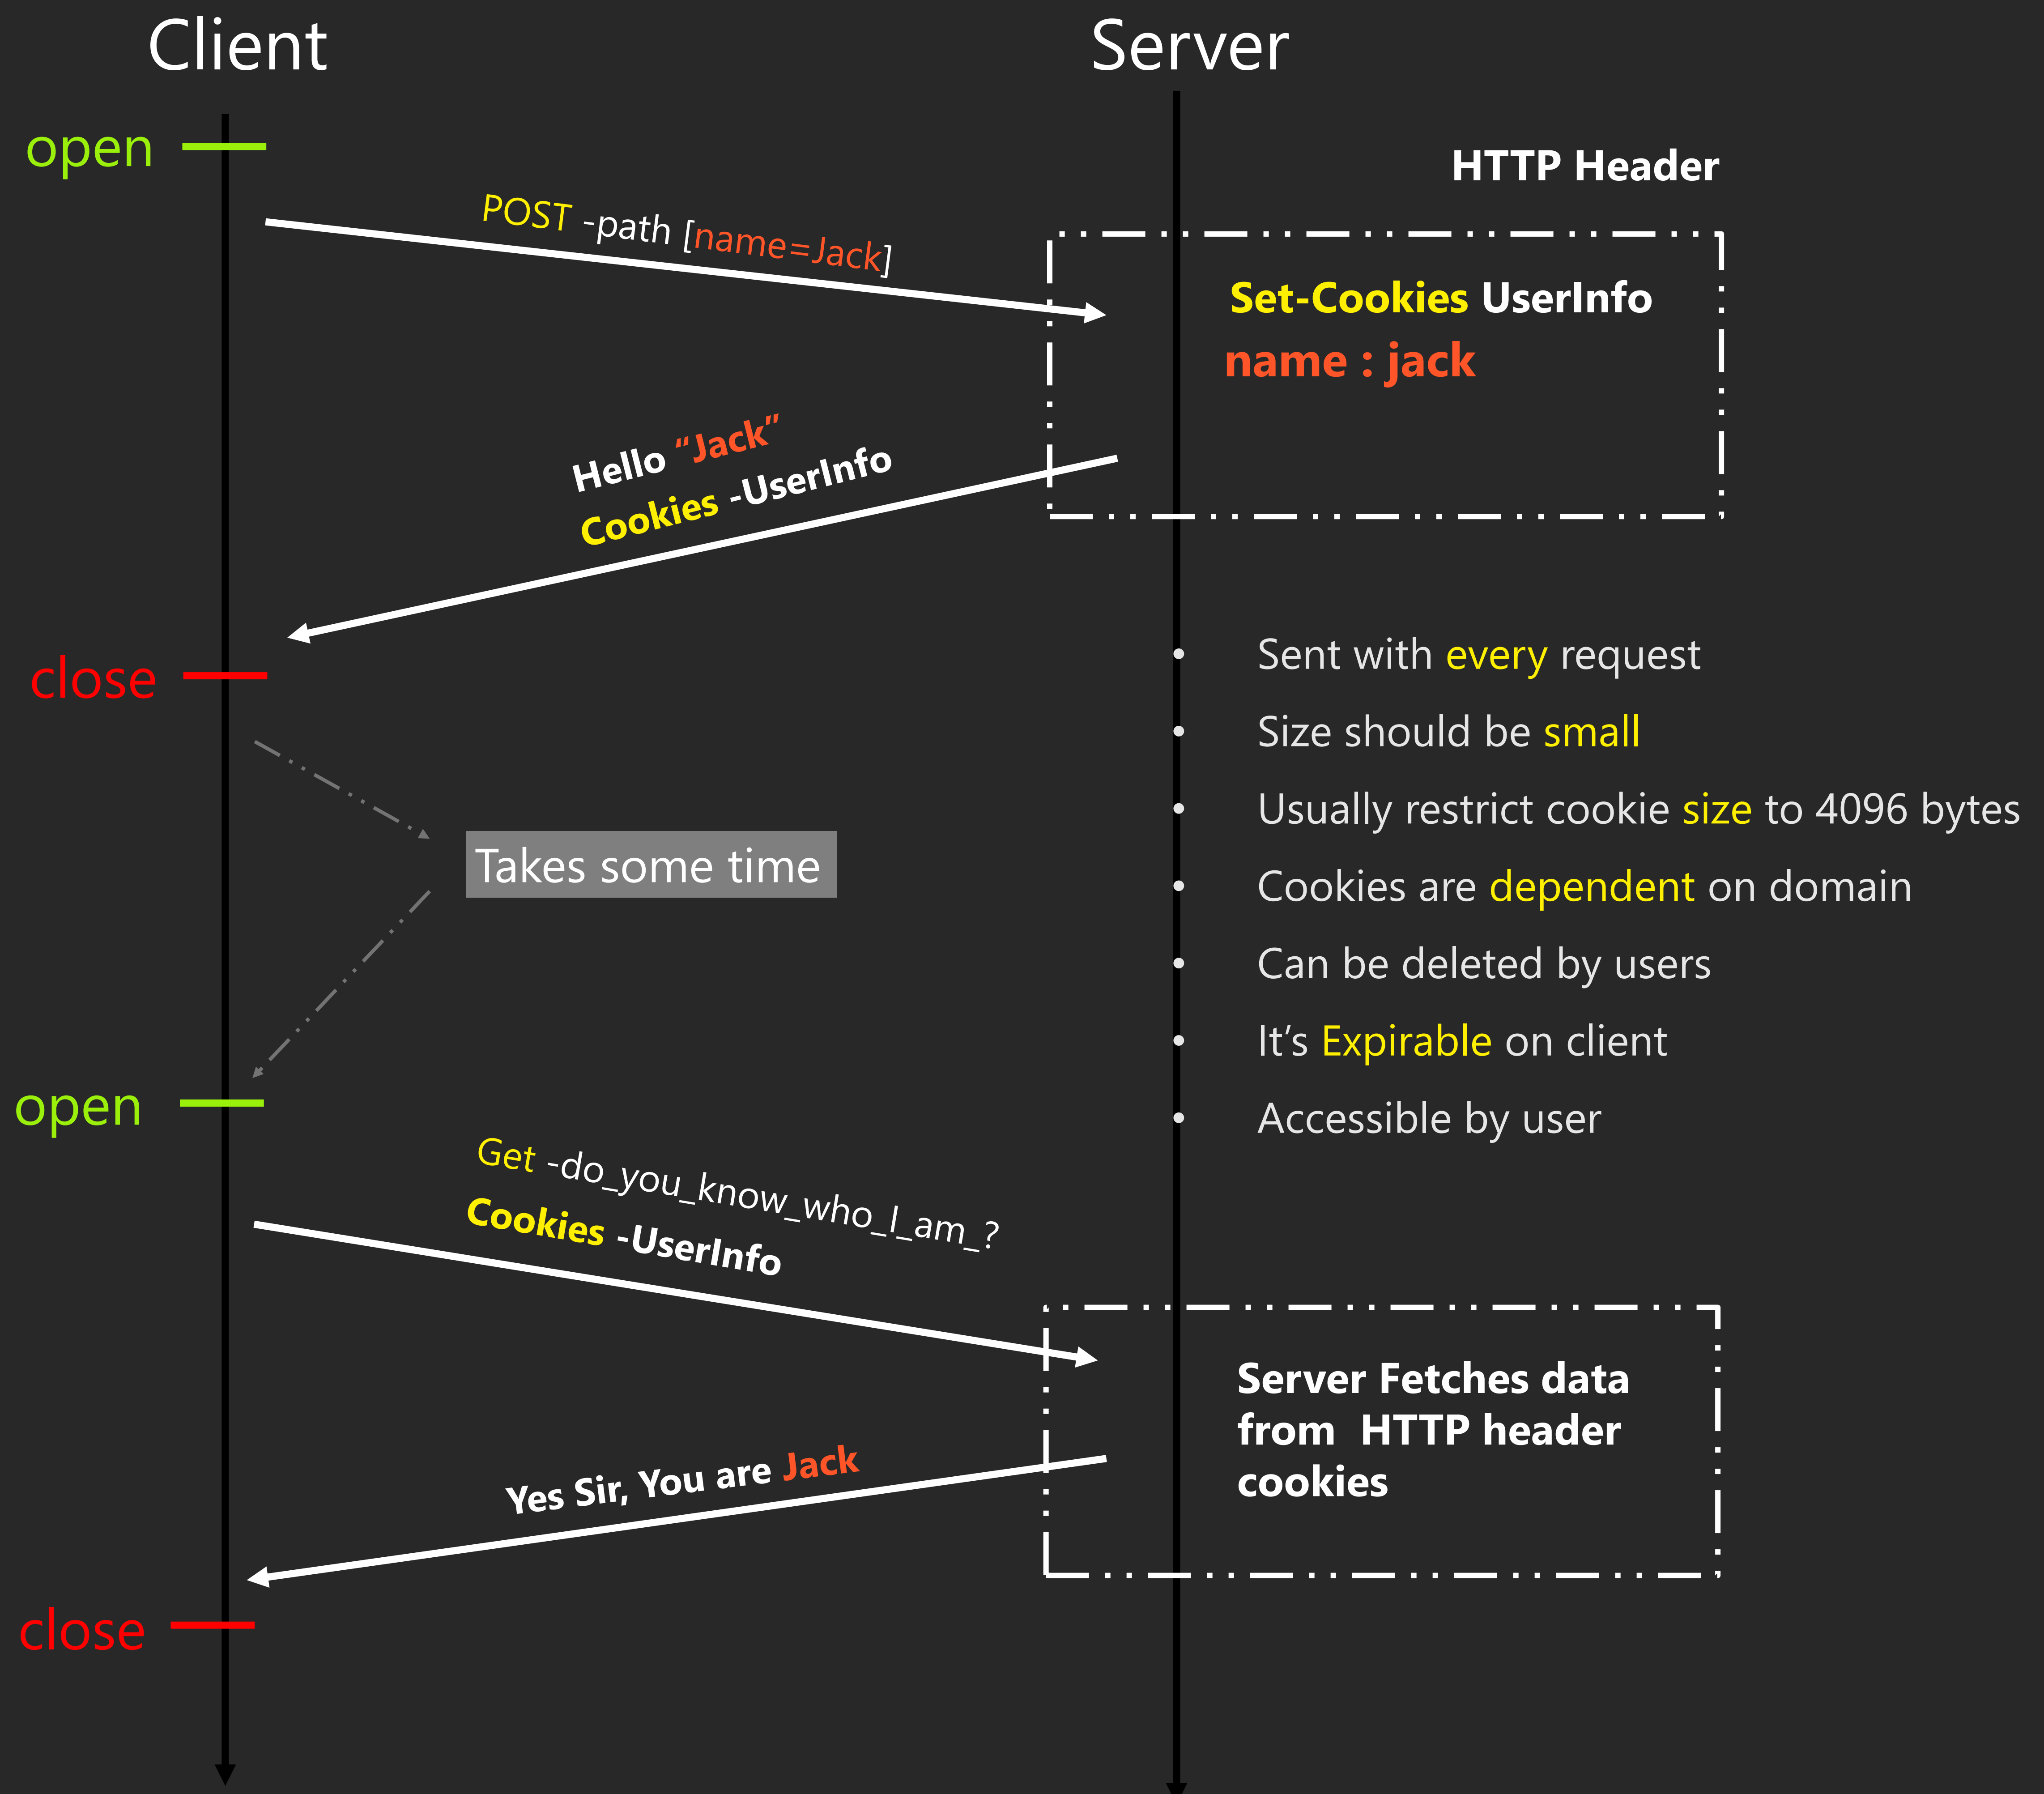

Query strings

Hidden fields

Each of these approaches has a specific usage and you can have all of them in one system.

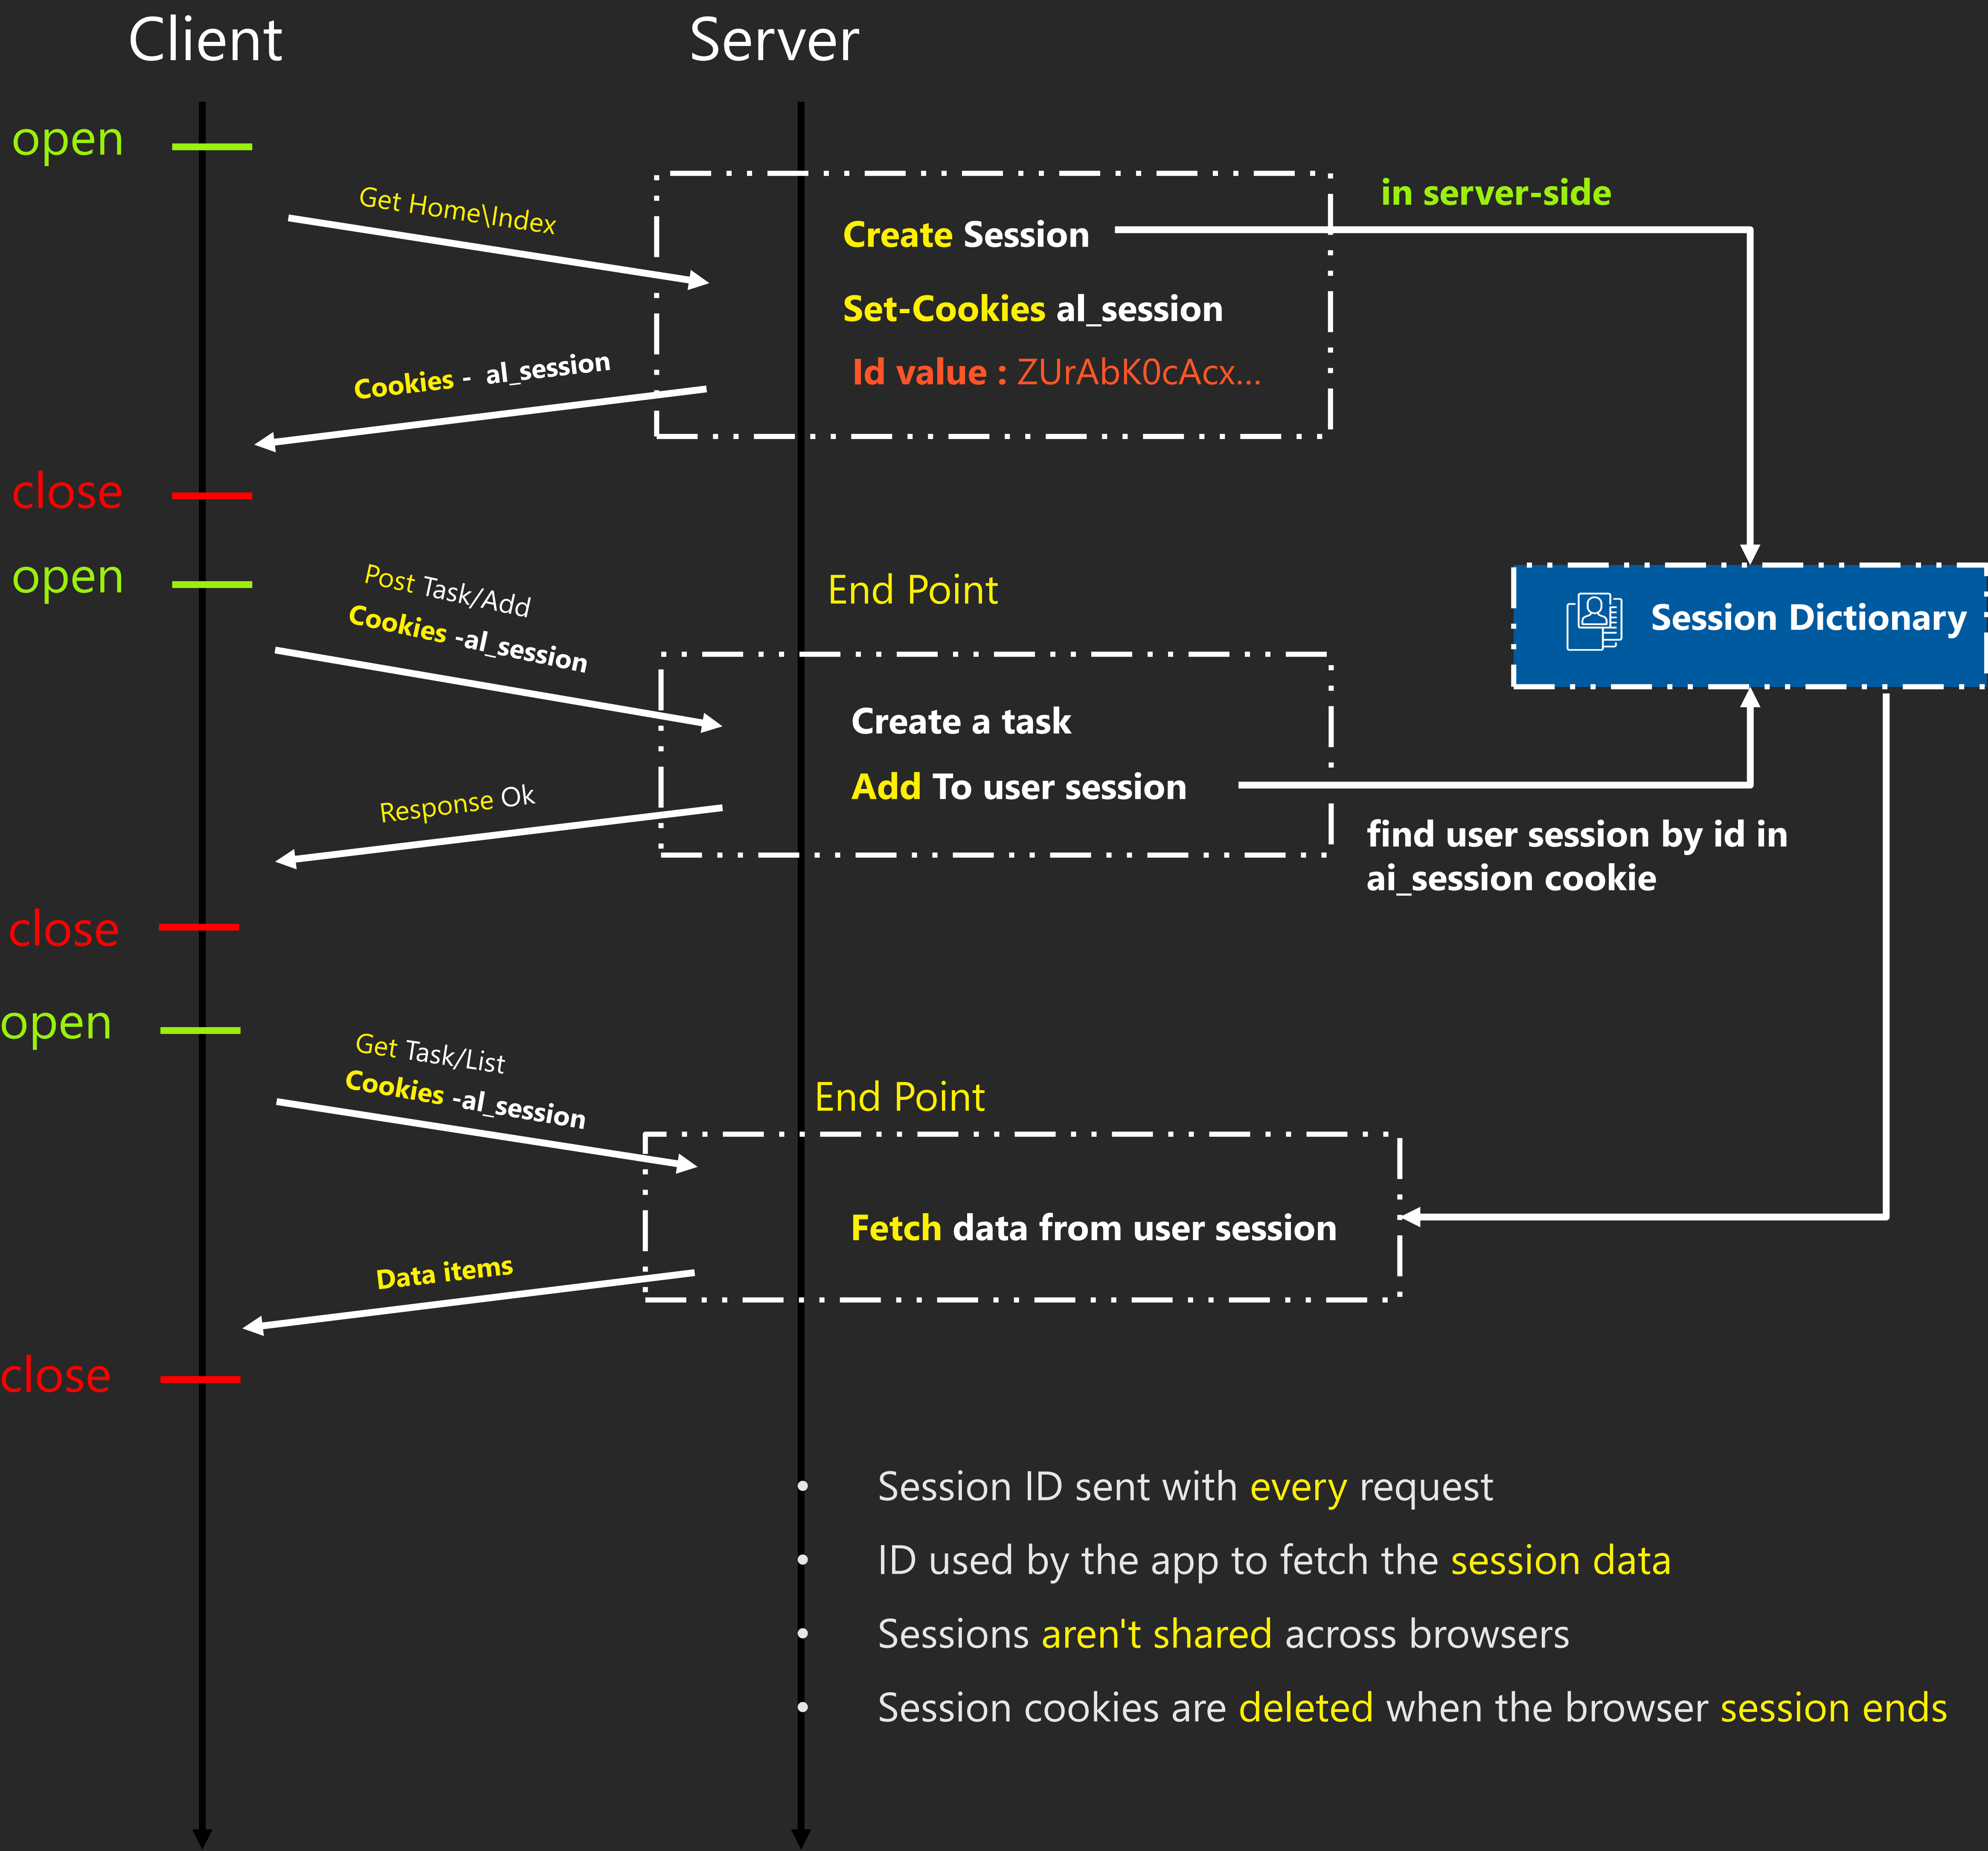

Cookies

Cookies are small files that server put on your Browser to store info about your preferences.

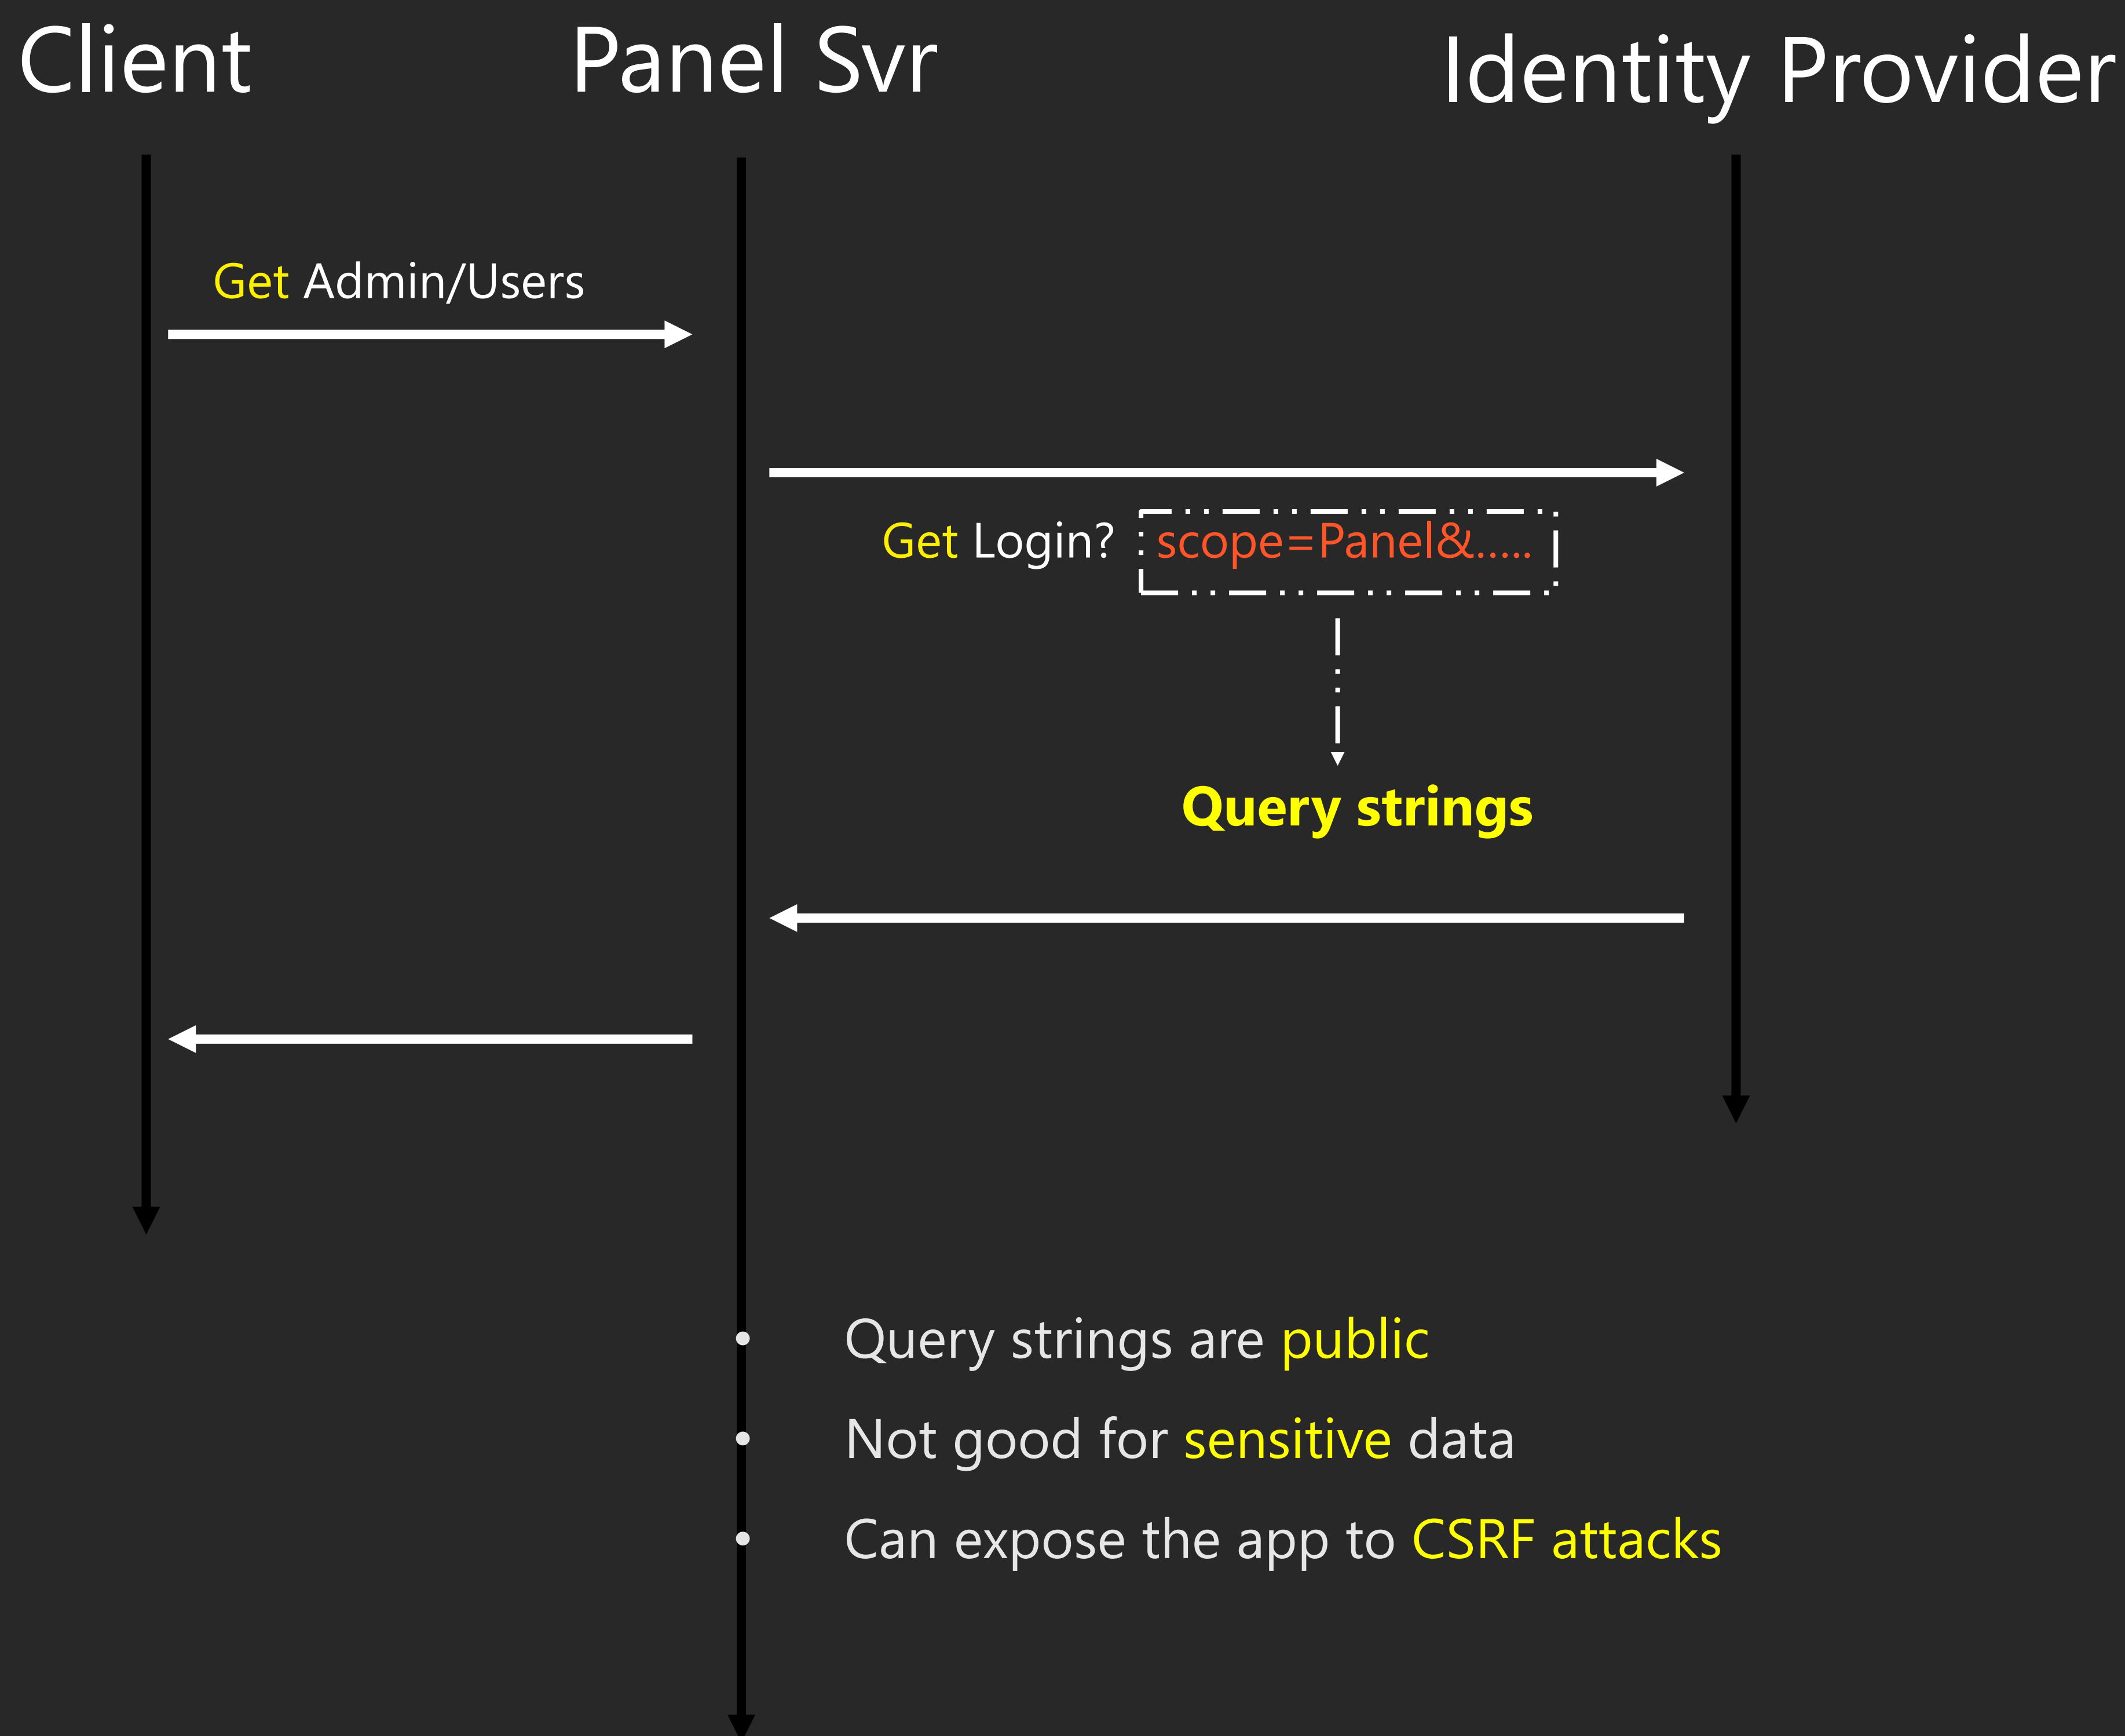

Session State

Server-side scenario for storage of user data while the user browses a web app.

Query strings

A limited amount of data can be passed from one request to another by adding it to the new request's query string.

Hidden fields

Data can be saved in hidden form fields and posted back on the next request.

Client

Panel Svr

Identity Provider

Get Home/Index

Response

```
<!DOCTYPE html>
<html lang="en">
<head>
  <meta charset="UTF-8">
</head>
<body>
  <div>
    <input type="text" name="SavedData" hidden>
  </div>
</body>
</html>
```

- This is common in multi-page forms
- Must always revalidate the fields
